Terminal velocity, steady speed achieved by an object freely falling through a gas or liquid. A typical terminal velocity for a parachutist who delays opening the chute is about 150 miles (240 kilometres) per hour.

terminal velocity | Definition, Examples, & Facts | Britannica
Terminal velocity is defined as the highest velocity that can be achieved by an object that is falling through a fluid, such as air or water. When terminal velocity is reached, the downward force of gravity is equal to the sum of the object's buoyancy and the drag force. An object at terminal velocity has zero net acceleration.

terminal velocity. Noun. maximum constant speed at which a falling body moves, achieved when the force of resistance to the medium (drag) is equal to the force of gravity.

at the start, the object accelerates downwards due to the force of gravity. as the object's speed increases, frictional forces such as air resistance or drag increase. at terminal velocity, the weight of the object due to gravity is balanced by the frictional forces, and the resultant force is zero.

Terminal velocity is the maximum velocity attainable by an object as it falls through a fluid (air is the most common example). It occurs when the sum of the drag force (F d) and the buoyancy is equal to the downward force of gravity (F G) acting on the object.

3. A new explicit relation for the terminal velocity. In his review of the empirical correlations for the drag coefficient, Goossens developed the following new landmark correlation between the drag coefficient and the terminal Reynolds number: (1) Cd = 24 Re t + 0.44 valid in the entire subcritical flow region Re t < 200,000.

Terminal Velocity of a Skydiver Find the terminal velocity of an 85-kg skydiver falling in a spread-eagle position. Strategy At terminal velocity, F net = 0. F net = 0. Thus, the drag force on the skydiver must equal the

force of gravity (the person’s weight). Using the equation of drag force, we find m g = 1 2 ρ C A v 2. m g = 1 2 ρ C A v 2.

The free-body diagrams are shown below for the instant in time in which they have reached terminal velocity. As learned above , the amount of air resistance depends upon the speed of the object. A falling object will continue to accelerate to higher speeds until they encounter an amount of air resistance that is equal to their weight.
